

SnapShield

Private multimodal security for the AI PC era.

- Local AI. Explainable decisions. Snapdragon-first deployment.
- See it. Analyze it. Protect it — privately.

The security surface changed

Attacks are no longer one-dimensional.

- SMS / email / chat
- Fake login pages and screenshots
- Suspicious URLs and QR codes
- Documents and attachments

One decision layer

Different inputs. One explainable security workflow.

- Perception → evidence → risk fusion → recommendation
- The user gets reasons, not just a scary score.
- Designed to keep sensitive content on-device.

Real AI, not a scripted demo

The working build uses a pretrained phishing transformer locally.

- Transformer classification
- URL structural inspection
- Urgency / credential / action-pressure evidence
- Evidence-weighted risk fusion
- No cloud AI API required for text analysis

Why Snapdragon

The hardware is part of the product.

- CPU: orchestration and system work
- GPU: visual workloads where useful
- Hexagon NPU: supported AI inference
- ONNX / QNN / Qualcomm AI runtime deployment path
- Measure NPU latency, memory and utilization on eligible hardware

Built around what Qualcomm winners demonstrate

The strongest edge-AI projects make the hardware materially useful.

- Real-time, on-device inference
- Privacy-sensitive workloads
- Heterogeneous CPU / GPU / NPU design
- AI Hub models to shorten deployment
- Measured performance instead of borrowed numbers

Deployment & proof

From prototype to reproducible edge application.

- Windows application with modular inference layer
- AI Hub / QNN compilation path
- NPU execution verification to avoid CPU fallback
- Benchmark: latency · memory · utilization · load time

The product advantage

Security becomes an AI-PC capability.

- Private by default
- Fast local decisions
- Explainable evidence
- Multimodal by architecture
- Designed for Snapdragon-powered HP PCs

SnapShield

See it. Analyze it. Protect it — privately.

- The cloud doesn't need to see your secrets to help protect them.
